Instructions:

- Due 09/24 at 5:00pm on Gradescope.
- You must follow the submission policy in the syllabus

Problem 1. Consider the matrix

$$\mathbf{A} = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} 3 & 0 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} \cos \pi/3 & -\sin \pi/3 \\ \sin \pi/3 & \cos \pi/3 \end{bmatrix}$$

- (a) Find an SVD $U\Sigma V^T$ of A. Hint: think about why the given factorization is not an SVD.
- (b) Draw what V^T does to the following points (here a point is anything shown in black, and the dotted lines represent the x and y axes.):

- (c) Draw what $\boldsymbol{\Sigma}\boldsymbol{V}^T$ does to the points.
- (d) Draw what $\boldsymbol{U}\boldsymbol{\Sigma}\boldsymbol{V}^T$ does to the points.

Problem 2. Recall:

$$\|\mathbf{A}\|_{2} = \max_{\mathbf{z} \neq 0} \frac{\|\mathbf{A}\mathbf{z}\|_{2}}{\|\mathbf{z}\|_{2}}, \qquad \|\mathbf{A}\|_{F}^{2} = \left(\sum_{i,j} [\mathbf{A}]_{i,j}^{2}\right)^{1/2}$$

We will prove the identity $\|\mathbf{A}\mathbf{B}\|_{\mathsf{F}} \leq \|\mathbf{A}\|_{2} \|\mathbf{B}\|_{\mathsf{F}}$.

- (a) Prove that $\|\mathbf{A}\mathbf{x}\|_2 \le \|\mathbf{A}\|_2 \|\mathbf{x}\|_2$ for any vector \mathbf{x} .
- (b) Suppose **X** is a $n \times m$ matrix. Write $\|\mathbf{X}\|_{\mathsf{F}}$ in terms of the column-norms $\|[\mathbf{X}]_{:,i}\|_{2}$.
- (c) Use (a) and (b) to prove the identity $\|\mathbf{A}\mathbf{B}\|_{\mathsf{F}} \leq \|\mathbf{A}\|_2 \|\mathbf{B}\|_{\mathsf{F}}$.

Problem 3. Let **A** be a $m \times n$ matrix with SVD $\mathbf{U}\Sigma\mathbf{V}^{\mathsf{T}}$ where Σ contains the singular values $\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_n$. We will prove that $\|\mathbf{A}\|_2 = \sigma_1$.

- (a) Prove that if $\mathbf{U}^{\mathsf{T}}\mathbf{U} = \mathbf{I}$ then $\|\mathbf{U}\mathbf{z}\|_{2} = \|\mathbf{z}\|_{2}$ for any vector \mathbf{z} .
- (b) Prove that if $V^TV = I$, then $V^Tx = 0$ if and only if x = 0.
- (c) Prove that $\|\mathbf{A}\|_2 = \|\mathbf{\Sigma}\|_2$.
- (d) It remains to show that $\|\mathbf{\Sigma}\|_2 = \sigma_1$.
 - (i) Compute $\|\mathbf{\Sigma}\mathbf{x}\|_2^2$ for an arbitrary vector $\mathbf{x} = [x_1, x_2, \dots, x_n]^\mathsf{T}$.
 - (ii) Show that $\|\mathbf{\Sigma}\mathbf{x}\|_{2}^{2} \leq \sigma_{1}^{2} \|\mathbf{x}\|_{2}^{2}$
 - (iii) Show that there exists a vector **x** such that $\|\mathbf{\Sigma}\mathbf{x}\|_2 = \sigma_1 \|\mathbf{x}\|_2^2$.
 - (iv) Conclude that $\|\mathbf{\Sigma}\|_2 = \sigma_1$.

Problem 4. Download the numpy data file from this link: https://drive.google.com/file/d/18Xf0029XXm3ENWfe3Z0a--Cf6tjyCViz/view?usp=drive_link

Use the following code to import the file into numpy.

```
import numpy as np
import matplotlib.pyplot as plt
im = np.load('change this path/CIMS.npy')
```

If you are using google colab, you can copy the CIMS.npy file to your own drive and then

```
from google.colab import drive
drive.mount('/content/gdrive')
im = np.load('gdrive/MyDrive/change this path/CIMS.npy')
```

In both cases, forma matrix from the image data.

```
A = np.mean(im,axis=2)
```

Here we obtain **A** by averaging the red, green, and blue channels of the image. This results in a black and white image.

(a) Plot the image using plt.imshow. You may want to use the colormap 'Greys_r' so that it looks like a greyscale image.

- (b) Compute the reduced SVD of **A**. You can use full_matrices=False to get the reduced SVD. This will be much faster than computing the full SVD.
 - For each k=1,10,100,200, make a plot of the best rank-k approximation \mathbf{A}_k to \mathbf{A} (i.e. via truncated SVD). Label each plot with the rank k as well as the relative error $\|\mathbf{A} \mathbf{A}_k\|_{\mathsf{F}} / \|\mathbf{A}\|_{\mathsf{F}}$
- (c) Remark on the quality of the plots.

How many numbers are required to store A? How many numbers are required to store the rank-k truncated SVD (as a factorization)?

Problem 5. Computing the SVD is expensive, but randomization can help us!

- (a) Randomized numerical linear algebra (RandNLA) is the study of the use of randomness in numerical linear algebra algorithms. One of the most famous randNLA algorithms is the randomized SVD. A simple version for approximating the SVD of a $m \times n$ matrix **A** can be described in several lines:
 - Choose a $n \times k$ matrix **R** with standard normal random entries
 - Compute X = AR
 - Compute \mathbf{Q}_{\prime} = REDUCED-SVD(\mathbf{X})
 - $\hat{\mathbf{U}}, \hat{\mathbf{\Sigma}}, \hat{\mathbf{V}}^{\mathsf{T}} = \text{REDUCED-SVD}(\mathbf{Q}^{\mathsf{T}}\mathbf{A})$:
 - Return approximate SVD of A: $(\mathbf{Q}\hat{\mathbf{U}})\hat{\mathbf{\Sigma}}\hat{\mathbf{V}}^{\mathsf{T}}$

Implement this algorithm with the same matrix A as in Problem 3. To generate the random matrix, you can use np.random.randn(n,k).

Again make sure to use full_matrices=False when computing the SVD of $\mathbf{Q}^{\mathsf{T}}\mathbf{A}$. Compare this to long the whole randomized SVD took (all of the steps) with k=100 against the time to compute the exact SVD in the previous problem.

- (b) Prove that the factors $\mathbf{Q}\hat{\mathbf{U}}$, $\hat{\mathbf{\Sigma}}$ and $\hat{\mathbf{V}}^T$ have the same properties as a SVD; i.e. $\mathbf{Q}\hat{\mathbf{U}}$ and $\hat{\mathbf{V}}$ have orthonormal columns and $\hat{\mathbf{\Sigma}}$ is diagonal with non-negative entires.
- (c) Make a plot of the rank k=100 truncated SVD (from problem 3) and the k=100 randomized SVD. Show the relative errors $\|\mathbf{A} (\mathbf{Q}\hat{\mathbf{U}})\hat{\mathbf{\Sigma}}\hat{\mathbf{V}}^{\mathsf{T}}\|_{\mathsf{F}}/\|\mathbf{A}\|_{\mathsf{F}}$ for each.
- (d) How long did this algorithm take to run vs. the reduced SVD in problem 3? Why was it so much faster? Hint: what are the dimensions of the matrices which we take the SVD of using this approach?
